

M4: before-forwarding admission gate

Later evidence checks

M4: committed record representation

Canonical bytes and candidate hashes are prepared before the transaction.
The evidence lane shows data dependencies and later sealing / checks.

Schema / insertion / readback failure → rollback + halt + no forwarding.
Ambiguous COMMIT → halt; no retry, database adoption or forwarding.
Post-commit mutation is outside the prevention guarantee; later sealing / verification
can detect divergence. SQLite persistence and external tool effects are not atomic.
Verification checks evidence consistency / origin; acceptance does not establish truth.
